Linear Regression

(find and work with a partner)

In the case of simple linear regression, for each example we have a single feature x and associated response (output) variable y. Our model is:

$$h_{w}(x) = w_0 + w_1 x$$

- 1. Name one goal of linear regression. Why would we want to fit a linear model?
- 2. In simple linear regression, how many features does each example have? How many parameters does our linear model have in this case?
 - # features (p) =
 - # model params =
- 3. What cost/loss function are we trying to minimize in simple linear regression?
- 4. Small example. Let n=2 and p=1, with the following data:

$$m{X} = egin{bmatrix} 1 \ 0 \end{bmatrix}, \quad m{y} = egin{bmatrix} 0 \ 1 \end{bmatrix}$$

Plot these two points – what should \hat{w}_0 and \hat{w}_1 be?

5. This week we derived the solution for simple linear regression:

$$\hat{w}_1 = \frac{\text{Cov}(\boldsymbol{x}, \boldsymbol{y})}{\text{Var}(\boldsymbol{x})} = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2} \qquad \hat{w}_0 = \bar{y} - \hat{w}_1 \bar{x}$$

where $\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i$ and $\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i$. Use these equations to compute \hat{w}_0 and \hat{w}_1 and verify your answer to the previous question.
